## ABSTRACT

An implementation of an improved Multiple-Original-Output ("Mopying") technology for multifunction devices (MFDs), described herein, enables a user at a computer to fully control and access the functions of a Mopy-enabled MFD. With this technology, the user fully controls the source (e.g. data and paper) for each Mopy of a Mopy job. Similarly, the user fully controls the destination (e.g. paper and communications) for each Mopy of a Mopy job. This abstract itself is not intended to limit the scope of this patent. The scope of the present invention is pointed out in the appending claims.
